

Gate Pass Monitoring System Using Web Development

ABSTRACT

A Gate Pass Monitoring System is a web-based application designed to digitize and streamline the process of issuing, verifying, and tracking gate passes within an organization. Traditional manual gate pass systems often lead to delays, unauthorized access, and difficulty in maintaining accurate records. This project addresses these challenges by providing an online platform where users can request gate passes, and administrators can review, approve, or reject requests in real time.

The system is developed using standard web technologies such as HTML, CSS, JavaScript for the frontend and Django with a SQLite database for the backend. Role-based access control ensures secure authentication for class advisors, security and HOD. Once approved, each gate pass is assigned with barcode in id card that can be scanned at the gate for quick verification. The system automatically logs entry and exit data, enabling real-time monitoring and generating reports for future reference.

By automating the gate pass workflow, the system enhances security, reduces paperwork, and improves operational efficiency. It provides a reliable, user-friendly, and scalable solution suitable for educational institutions, corporate offices, and residential complexes.
